

**Application  
for  
United States Letters Patent**

09560372.042800

**To all whom it may concern:**

*Be it known that I,*

Alan R. Tall

*have invented certain new and useful improvements in*

HUMAN ABC1 PROMOTER AND ASSAYS BASED THEREON

*of which the following is a full, clear and exact description.*

**HUMAN ABC1 PROMOTER AND ASSAYS BASED THEREON**

5

This invention has been made with government support under National Institutes of Health Grant No. HL-54591. Accordingly, the U.S. Government may have certain rights in the invention.

- 10 Throughout this application, various publications may be referenced by Arabic numerals in brackets. Full citations for these publications may be found at the end of the specification immediately preceding the claims. The disclosures of these publications in their entireties are hereby incorporated by  
15 reference into this application in order to more fully describe the state of the art as known to those skilled therein as of the date of the invention described and claimed herein.

**Field of Invention**

- 20 This invention discloses a sterol-responsive region of the human ABC1 promoter, and shows that it is activated by hydroxysterols and 9-cis-retinoic acid, implicating a mechanism of activation involving LXR/RXR heterodimers. Also disclosed is the functionally active form of the ABC1 cDNA.

25

**Background of the Invention**

- Plasma HDL-C levels are inversely related to the incidence of coronary artery disease (1). Two genetic diseases illustrate this phenomenon: the rare Tangier Disease and the more common  
30 familial HDL deficiency. Tangier disease is characterized by an extremely low concentration of circulating HDL and the accumulation of cholesteryl esters in tonsils, liver, spleen and intestinal mucosa, mostly in macrophage foam cells (2). Patients with familial HDL deficiency exhibit a low  
35 concentration of HDL particles and an increased risk of coronary artery disease (3). A common explanation for the

09560372.042800

cardioprotective effect of HDL is the major role they play in reverse cholesterol transport (4). It is commonly accepted that the efflux of cholesterol from cells is due to two different pathways: the first is passive and promotes efflux from the cell membrane to HDL, and the second is energy-dependent and apolipoprotein-mediated (5). The latter was characterized in fibroblasts and macrophages, and involves lipid-poor or lipid-free apolipoproteins such as apoA-I, apoA-II and apo-E (5). This active pathway has been reported to be defective in both Tangier disease and familial HDL deficiency (6-7). It was recently shown that ABC1 is a key gene in this process (8) and that mutations in this gene are the major cause of Tangier disease and familial HDL deficiency (3, 9-14).

ABC1 (ABCA1) belongs to the large ATP-Binding Cassette transporter family. These transmembrane proteins transport many substrates across membranes thanks to a channel-like topology (15-16). The human ABC1 gene was assigned to chromosome 9q31, spanning a minimum of 70 kb and containing at least 49 exons (11, 13, 17). While its expression is ubiquitous, the highest levels of human or murine mRNAs were found in placenta, liver, lung, adrenal glands and fetal tissues (18, 19). The predicted human protein contains 2201 amino acids (220 kDa) (18).

The expression of hABC1 is induced during differentiation of human monocytes to macrophages and as a result of cholesterol loading. In human macrophages, both the protein and the mRNA are upregulated in the presence of acetylated LDL (acLDL), and downregulated by cholesterol unloading via HDL3 (18). While the cholesterol-mediated downregulation of genes involved in cholesterol uptake or biosynthesis is well understood (20), mechanisms of sterol-mediated upregulation of gene expression are more poorly understood. Two families of nuclear receptors are known to be activated by oxysterols and to mediate a positive response by binding to specific DNA elements: Liver-X-

00560372.042800

Receptor (LXR) and Steroidogenic Factor 1 (SF1) (21), (22),  
(23), (24). SF1 acts as a monomer and has been implicated, for  
example, in the regulation of steroidogenic acute regulatory  
protein gene expression (StAR) (23). Recently, two different  
5 genes involved in reverse cholesterol transport pathways, cyp7a  
(21) and CETP (22), have been shown to be upregulated by the  
heterodimer LXR-RXR (Liver-X-Receptor and Retinoid-X-Receptor).  
This suggests the hypothesis that LXRs might coordinate  
different steps of these pathways (22). LXR $\alpha$  (NR1H3) and LXR $\beta$   
10 (NR1H2) heterodimerize with their partner RXR to upregulate  
genes through binding sites composed of direct repeats (DR)  
spaced by 4 (LXR $\alpha$  and LXR $\beta$ ) or 1 nucleotide (LXR $\beta$ ) (25-27). The  
dimer can be activated by both the ligands of RXR (retinoids)  
and LXR (oxysterols), separately or together (26, 28, 29).

15 However, none of the cited references disclose the sequence of  
the hABC1 promoter, nor do they define its function or  
activation by transcription factors or small organic molecules.

Summary of the Invention

This disclosure provides an isolated human ABC1 promoter capable of directing transcription of a heterologous coding sequence positioned downstream therefrom, wherein the promoter is:

- (a) a promoter comprising the nucleotide sequence shown in SEQ ID NO: 1 ;
- (b) a promoter comprising a nucleotide sequence functionally equivalent to the nucleotide sequence shown in SEQ ID NO: 1; or
- (c) a promoter comprising a nucleotide sequence that hybridizes to a sequence complementary to the promoter of (a) or (b) in a Southern hybridization reaction performed under stringent conditions.

This disclosure also provides a recombinant expression construct effective in directing the transcription of a selected coding sequence which comprises:

- (a) a human ABC1 promoter nucleotide sequence according to claim 1; and
- (b) a coding sequence operably linked to the promoter, whereby the coding sequence can be transcribed and translated in a host cell, and the promoter is heterologous to the coding sequence.

This disclosure also provides a method for expressing foreign DNA in a host cell which comprises introducing into the host cell a gene transfer vector comprising the discussed ABC1 promoter operably linked to a foreign DNA encoding a desired polypeptide or RNA, wherein said foreign DNA is expressed.

The disclosure also provides a method of determining whether a chemical not previously known to be a modulator of the human ABC1 gene transcriptionally modulates the expression of the human ABC1 gene which comprises:

- (a) contacting a sample which contains a predefined number of

09560372-042800

identical eucaryotic cells with a predetermined concentration of the chemical to be tested, each cell comprising a DNA construct consisting essentially of in 5' to 3' order,

- 5 (i) a modulatable transcriptional regulatory sequence of the *ABC1* gene,
- (ii) the *ABC1* promoter of claim 1, and
- (iii) a reporter gene which expresses a polypeptide that produces a detectable signal, coupled to, and under the control of, the *ABC1* promoter, under conditions wherein the chemical if capable of acting as a transcriptional modulator of the *ABC1* gene, causes a detectable signal to be produced by the polypeptide expressed by the reporter gene;
- 10 (b) quantitatively determining the amount of the signal produced in (a); and
- (c) comparing the amount of signal determined in (b) with the amount of signal produced and detected in the absence of any chemical being tested or with the amount of signal produced and detected upon contacting the sample in (a) with other chemicals,
- 20 thereby identifying the test chemical as a chemical which causes a change in the amount of detectable signal produced by the polypeptide expressed by the reporter gene, and determining whether the test chemical specifically transcriptionally modulates expression of the human *ABC1* gene.

25 This disclosure also provides a method of treating atherosclerosis in a subject which comprises administering to the subject a therapeutically effective amount of a chemical selected by the method discussed above to modulate expression of the human *ABC1* gene.

30

This disclosure also provides a transgenic non-human mammal whose germ or somatic cells contain the promoter described herein introduced into the mammal, or an ancestor thereof, at an embryonic stage. The mammal may be a mouse.

35

09560372-042800

This disclosure also provides a compound which modulates expression of the human *ABC1* gene, which has been identified by the method discussed above.

- 5 This disclosure also provides an isolated human *ABC1* gene comprising six exons and the promoter described.

Thus, disclosed is the sequence of the h*ABC1* promoter and its 5' untranslated region, with 3 new exons, differentially  
10 expressed and carrying two alternative start codons. This promoter is active in macrophages. Also, the full length cDNA, incorporating the 3 new exons plus the published cDNA sequence, is active in promoting efflux of cholesterol from cells, while the published cDNA sequence alone is not. Also disclosed is  
15 that RXR $\alpha$  and LXR $\alpha$  or LXR $\beta$  are able to activate *in vitro* this promoter and the response is increased by oxysterols and/or 9-*cis*-retinoic acid (9CRA).

003270-27E09560

### Description of the Figures

**Figure 1** shows the expression of hABC1 in THP1 macrophages. THP-1 cells were exposed for 72h to phorbol 12-myristate 13-acetate to induce their differentiation in macrophages. On day 4, cells were treated for 24h with vehicle (ethanol), 22(R)-Hch (10 mM) and / or 9CRA (10 mM) (n=4 per treatment). A Northern blot was performed with 40 µg of total RNA from each sample. The membrane was hybridized with hABC1 probe and mG3PDH as an internal standard. The Mann Whitney test was used to analyse the difference between "ethanol" and "treatment", \* p< 0.05.

**Figures 2A-2C** show the analysis of the hABC1 5' sequence. **Figure 2A** shows the gene organization. The hABC1 promoter was cloned from the human library RPCI-11, and the structure of its 5' end was determined. **Figure 2B** shows the results of 5' RACE PCR. A 5' RACE PCR was performed on cholesterol-loaded THP-1 macrophages. These cells express exon 1 and 2 (transcript A). A 5' RACE PCR was also conducted on HepG2 cells which express a truncated version of exon 2 and also exon 3 (transcripts B, C, D). Two ATG are present in exon 2 and 3. **Figure 2C** shows the NH2 terminal sequence. A comparison of the deduced NH2 terminal sequence of hABC1 with the nucleotide database (tBlastn) revealed similarities with two members of the ABC1 family: ABCR and ABC3. A,B = SEQ ID NO: 2; C,D = SEQ ID NO: 3; amino acids 6-61 of hABC1 = SEQ ID NO: 4; amino acids 6-61 of hABCR = SEQ ID NO: 6; amino acids 1-44 of hABC1 = SEQ ID NO: 5; and amino acids 1-44 of hABC3 = SEQ ID NO: 7.

**Figure 3** shows the hABC1 promoter sequence (SEQ ID NO: 1). This sequence is identical to the working draft sequence of the genomic clone RPM11-1M10 (position 2335 bp to 3463 bp, genebank accession number AC012230) except for the italicized 5' end which is new. The fragment used in transfections covers -928 bp to

09560372.042800

+101 bp. An arrow indicated at -469 bp is the *SacI* site that was used to generate a deleted promoter fragment. An analysis of the sequence (MatInspector) revealed numerous putative transcription binding sites (underlined, dashed lines indicate a site on the complementary strand). The bold type represents the 5' end of exon 1.

**Figure 4** shows the expression of *LXRα* and *LXRβ* in mouse peritoneal macrophages (PM), RAW 264.7 cells, 293 cells and CV-1 cells. Cells were isolated and cultured as described in "Material and methods". A Northern blot was performed with 35 µg of total RNA of each cell line. Hybridizations were performed using probes of similar specific activities, *hLXRα*, *mLXRβ* and *mG3PDH* as an internal standard.

15

**Figures 5A-5C** show activation of the *hABC1* promoter by oxysterols and retinoic acid in RAW 264.7 cell. In **Figure 5A** a fragment of the *hABC1* promoter (-828 bp to +101 bp) was linked to Firefly luciferase reporter gene. The resulting plasmid was cotransfected with a control reporter plasmid (*Renilla* luciferase) in the mouse macrophage-like RAW 264.7 cells. Four independent transfections experiments (each in triplicates) were performed. The results are expressed as a ratio between the Firefly and *Renilla* luciferase activities. Cells were treated with vehicle or 22(R)-Hch (10 µM), 9CRA (10 µM) and 22(R)-Hch (10 µM) + 9CRA (10 µM), 24 hours in FBS medium complemented with 10% LPDS. **Figure 5B** shows deletional analysis of *hABC1* promoter. Two independent experiments in triplicate were performed according to the protocol described in (a), using a shorter promoter: -456 pb +101 pb. **Figure 5C** shows activation of *hABC1* promoter by various oxysterols and/or 9CRA. The same experiments as (a) were performed using 22(R)-Hch (10 µM), 25-Hch (10 µM), 7K-Ch (10 µM) and 9CRA (10 µM). Three to four

09560372.042800

independent experiments in duplicate or triplicate were performed. Mann Whitney tests were mean to analyze the difference between "Ethanol" and "Treatment". In these Figures, \*\*\*=  $P < 0.001$ , \*=  $P < 0.05$ .

5

**Figures 6A and 6B** show Sterol and LXR/RXR activation of the hABC1 promoter in 293 cells. In **Figure 6A** 293 cells were transfected with the hABC1 promoter (-469 bp +101 bp) or in **Figure 6B** a construct containing 3 copies of the LXR responsive element of the CETP promoter (22). These constructs were cotransfected with the *Renilla* luciferase reporter gene and hLXR $\alpha$ , mLXR $\beta$ , hRXR $\alpha$ . The cells were treated 24 h with vehicle alone or 22(R)-Hch (10  $\mu$ M) and/or 9CRA (10  $\mu$ M) in FBS medium + 10% LPDS. The results represent two independent experiments in 15 duplicates for the transfections using the hABC1 promoter and one to two experiments in duplicate for the transfections using the hCETP promoter.

**Figure 7** shows transactivation of the hABC1 promoter by LXR/RXR 20 in CV-1 cells. CV-1 cells were transfected and treated according to the protocols described in Figure 5. Two to three independent experiments in duplicates were performed. Mann Withney tests analyse the difference between "Ethanol" and "Treatment". \*\*= $P < 0.05$ .

25

**Figures 8A and 8B** show expression studies showing that full length cDNA, including exons 1, 2, and 3 (Figure 2) is active in promoting cholesterol efflux from cells while published cDNA is inactive. HEK 293 cells were plated in 12 well cell culture 30 plates the day before transfection. Next day, cells about 95% confluence were transfected using Lipofectamine 2000 (GIBCO-BRL, MD) and corresponding plasmid constructs. The cells were labeled for 20 hours with  $^3\text{H}$ -cholestereol at 0.5  $\mu\text{Ci/ml}$  in DMEM media plus 10% FBS. Then, cells were washed 3 times with PBS

09560372.042800

and equilibrated in DMEM media plus 0.2% fatty free BSA for 3 hours. The media were replaced with fresh DMEM, 0.2% BSA media in the presence or absence of 10  $\mu$ g/ml human apolipoprotein AI. After 6 hours incubation, the media and cells were separately  
5 collected and the cholesterol efflux was measured as a percentage of 3H-cholesterol efflux over total cellular labeling. **Figure 8A** shows results of a study using Genbank Accession X75926, where the methionine 61 was originally designated as the start methionine. This version of cDNA is  
10 inactive in stimulating cholesterol efflux. **Figure 8B** shows results of a study using the full length version, including exons 1-3, encoding an additional 60 amino acids, which is active in promoting cholesterol efflux to apoA1.

Detailed Description of the Invention

- The practice of the present invention will employ, unless otherwise indicated, conventional techniques of molecular biology, microbiology, virology, recombinant DNA technology, and immunology, which are within the skill of the art. Such techniques are explained fully in the literature. See, e.g., Sambrook, Fritsch & Maniatis, Molecular Cloning: A Laboratory Manual, -Second Edition (1989); DNA Cloning, Vols. I and II (D. N. Glover ed. 1985); Oligonucleotide Synthesis (M. J. Gait ed. 1984); Nucleic Acid Hybridization (B. D. Hames & S. J. Higgins eds. 1984); Animal Cell Culture (R. K. Freshney ed. 1986); Immobilized Cells and Enzymes (IRL press, 1986); Perbal, B., A Practical Guide to Molecular Cloning (1984); the series, Methods In Enzymology (S. Colowick and N. Kaplan eds., Academic Press, Inc.); and Handbook of Experimental Immunology, Vols. I-IV (D. M. Weir and C. C. Blackwell eds., 1986, Blackwell Scientific Publications).
- 20 This disclosure provides an isolated human *ABC1* promoter capable of directing transcription of a heterologous coding sequence positioned downstream therefrom, wherein the promoter is:
- (a) a promoter comprising the nucleotide sequence shown in SEQ ID NO: 1 ;
  - 25 (b) a promoter comprising a nucleotide sequence functionally equivalent to the nucleotide sequence shown in SEQ ID NO: 1; or
  - (c) a promoter comprising a nucleotide sequence that hybridizes to a sequence complementary to the promoter of (a) or (b)
  - 30 in a Southern hybridization reaction performed under stringent conditions.

The promoter may be a nucleotide sequence that is at least 87% homologous to SEQ ID NO: 1, preferably 90% homologous to SEQ ID NO: 1, most preferably at least 95% homologous to SEQ ID NO: 1.

09560372.042800

This disclosure also provides a recombinant expression construct effective in directing the transcription of a selected coding sequence which comprises:

(a) a human ABC1 promoter nucleotide sequence according to claim 1; and

(b) a coding sequence operably linked to the promoter, whereby the coding sequence can be transcribed and translated in a host cell, and the promoter is heterologous to the coding sequence.

10 The recombinant expression construct may further have a coding sequence that encodes a transporter polypeptide. The transporter polypeptide may be ABCA1 transmembrane transporter protein.

15 The recombinant expression construct may further comprise a nucleic acid segment encoding a transactivator protein capable of upregulating the ABC1 promoter. The transactivator protein may be the Liver-X-Receptor, the Retinoid-X-Receptor, or a heterodimer of the Liver-X-Receptor and the Retinoid-X-Receptor.

20 This disclosure also provides a host cell which comprises the recombinant expression construct discussed above. The host cell may be stably transformed with the recombinant expression construct.

25 The host cell may be a macrophage, an immortalized cell, a RAW cell, an African green monkey CV-1 cell, or a human 293 cell.

This disclosure also provides a method for expressing foreign DNA in a host cell which comprises introducing into the host cell a gene transfer vector comprising the discussed ABC1 promoter operably linked to a foreign DNA encoding a desired polypeptide or RNA, wherein said foreign DNA is expressed.

35 The promoter nucleotide sequence may be a nucleotide sequence functionally equivalent to the ABC1 promoter sequence

009240-2409560

represented in SEQ ID NO: 1.

In the method, the gene transfer vector may encode and express a reporter molecule. The reporter molecule may be selected from the group consisting of beta-galactosidase, beta-glucuronidase, luciferase, chloramphenicol acetyltransferase, neomycin phosphotransferase, and guanine xanthine phosphoribosyltransferase.

10 The vector may be introduced into the cell adenovirus infection, liposome-mediated transfer, topical application to the cell, or microinjection.

The method may further comprise introducing into the cell a gene transfer vector comprising a nucleic acid segment encoding a transactivator protein capable of upregulating the ABC1 promoter. The transactivator protein may be the Liver-X-Receptor, the Retinoid-X-Receptor, or a heterodimer of the Liver-X-Receptor and the Retinoid-X-Receptor.

20 The method may also comprise contacting the cell with a transactivator protein capable of upregulating the ABC1 promoter. The transactivator protein may be the Liver-X-Receptor, the Retinoid-X-Receptor, or a heterodimer of the Liver-X-Receptor and the Retinoid-X-Receptor.

The method may also comprise contacting the cell with an agonist of the Liver-X-Receptor, of the Retinoid-X-Receptor, or of a heterodimer of the Liver-X-Receptor and the Retinoid-X-Receptor.

30 The disclosure also provides a method of determining whether a chemical not previously known to be a modulator of the human ABC1 gene transcriptionally modulates the expression of the human ABC1 gene which comprises:

35 (a) contacting a sample which contains a predefined number of identical eucaryotic cells with a predetermined concentration

00560372-042800

of the chemical to be tested, each cell comprising a DNA construct consisting essentially of in 5' to 3' order,

- (i) a modulatable transcriptional regulatory sequence of the *ABC1* gene,
- 5 (ii) the *ABC1* promoter of claim 1, and
- (iii) a reporter gene which expresses a polypeptide that produces a detectable signal, coupled to, and under the control of, the *ABC1* promoter, under conditions wherein the chemical if capable of acting as a transcriptional
- 10 modulator of the *ABC1* gene, causes a detectable signal to be produced by the polypeptide expressed by the reporter gene;
- (b) quantitatively determining the amount of the signal produced in (a); and
- 15 (c) comparing the amount of signal determined in (b) with the amount of signal produced and detected in the absence of any chemical being tested or with the amount of signal produced and detected upon contacting the sample in (a) with other chemicals, thereby identifying the test chemical as a chemical which causes
- 20 a change in the amount of detectable signal produced by the polypeptide expressed by the reporter gene, and determining whether the test chemical specifically transcriptionally modulates expression of the human *ABC1* gene.

- 25 In the method, each cell may express a transactivator protein capable of upregulating the *ABC1* promoter. The transactivator protein may be any of the ones previously mentioned.

The method may also comprise contacting the cells with a

30 transactivator protein capable of upregulating the *ABC1* promoter.

In the method, the sample may comprise identical cells in monolayers, or cells in suspension. The identical cells

35 comprise human, animal, or plant cells. The predefined number of identical cells may be from about 1 to about  $5 \times 10^5$  cells,

09560372.042800

preferably from about 1.0 pM to about 20  $\mu$ M, more preferably from about 10 nM to about 500  $\mu$ M.

In the method, the contacting may be effected from about 1 hour to about 24 hours. The contacting may be effected with more than one predetermined concentration of the molecule to be tested.

In the method, the modulatable transcriptional regulatory sequence may comprise a cloned genomic regulatory sequence.

The DNA construct may consist of more than one modulatable transcriptional regulatory sequence.

15 In the method, the reporter gene may be inserted downstream of the ABC1 promoter by homologous recombination. The reporter gene may encode a luciferase, chloramphenicol acetyltransferase, beta-glucuronidase, beta-galactosidase, neomycin phosphotransferase, or guanine xanthine  
20 phosphoribosyltransferase. Preferably, the reporter gene is the ABC1 gene.

This disclosure also provides a method of treating atherosclerosis in a subject which comprises administering to  
25 the subject a therapeutically effective amount of a chemical selected by the method discussed above to modulate expression of the human ABC1 gene.

This disclosure also provides a method of simultaneously  
30 screening a plurality of test chemicals to determine whether the chemicals are capable of transcriptionally modulating the ABC1 gene which comprises simultaneously screening the test chemicals against each of the genes of interest according to the method discussed above.

This disclosure also provides a transgenic non-human mammal whose germ or somatic cells contain the promoter described herein introduced into the mammal, or an ancestor thereof, at an embryonic stage. The mammal may be a mouse.

5

This disclosure also provides a compound which modulates expression of the human ABC1 gene, which has been identified by the method discussed above.

10 This disclosure also provides an isolated human ABC1 gene comprising six exons and a promoter, wherein the promoter is selected from the group consisting of:

(a) a promoter comprising the nucleotide sequence shown in SEQ ID NO: 1 ;

15 (b) a promoter comprising a nucleotide sequence functionally equivalent to the nucleotide sequence shown in SEQ ID NO: 1; and

(c) a promoter comprising a nucleotide sequence that hybridizes to a sequence complementary to the promoter of (a) or (b) in a Southern hybridization reaction performed under stringent conditions.

20

#### Definitions

As used herein "nucleic acid molecule" includes both DNA and RNA and, unless otherwise specified, includes both double-stranded and single-stranded nucleic acids. Also included are hybrids such as DNA-RNA hybrids. Reference to a nucleic acid sequence can also include modified bases as long as the modification does not significantly interfere either with binding of a ligand such as a protein by the nucleic acid or Watson-Crick base pairing.

30

Two DNA or polypeptide sequences are "substantially homologous" when at least about 80% (preferably at least about 90%, and most preferably at least about 95%) of the nucleotides or amino acids

09560372.042800

match over a defined length of the molecule. As used herein, "substantially homologous" also refers to sequences showing identity to the specified DNA or polypeptide sequence. DNA sequences that are substantially homologous can be identified in a Southern hybridization, experiment under, for example, stringent conditions, as defined for that particular system. Defining appropriate hybridization conditions is within the skill of the art. See, e.g., Sambrook et al., supra; DNA Cloning, vols I & II, supra; Nucleic Acid Hybridization, supra.

10

A sequence "functionally equivalent" to an ABC1 promoter sequence is one which functions in the same manner as the ABC1 promoter sequence. Thus, a promoter sequence "functionally equivalent" to the ABC1 promoter described herein is one which is capable of directing transcription of a downstream coding sequence in substantially similar timeframes of expression and in substantially similar amounts and with substantially similar tissue specificity as the ABC1 promoter.

A DNA "coding sequence" or a "nucleotide sequence encoding" a particular protein, is a DNA sequence which is transcribed and translated into a polypeptide *in vivo* or *in vitro* when placed under the control of appropriate regulatory sequences. The boundaries of the coding sequence are determined by a start codon at the 5'-(amino) terminus and a translation stop codon at the 3'-(carboxy) terminus. A coding sequence can include, but is not limited to, procaryotic sequences, cDNA from eucaryotic mRNA, genomic DNA sequences from eucaryotic (e.g., mammalian) sources, viral RNA or DNA, and even synthetic nucleotide sequences. A transcription termination sequence will usually be located 3' to the coding sequence.

DNA "control sequences" refers collectively to promoter sequences, polyadenylation signals, transcription termination

00550372.042300

sequences, upstream regulatory domains, enhancers, and the like, untranslated regions, including 5'-UTRs and 3'-UTRs, which collectively provide for the transcription and translation of a coding sequence in a host cell.

5

"Operably linked" refers to an arrangement of nucleotide sequence elements wherein the components so described are configured so as to perform their usual function. Thus, control sequences operably linked to a coding sequence are capable of effecting the expression of the coding sequence. The control sequences need not be contiguous with the coding sequence, so long as they function to direct the expression thereof. Thus, for example, intervening untranslated yet transcribed sequences can be present between a promoter sequence and the coding sequence and the promoter sequence can still be considered "operably linked" to the coding sequence.

A control sequence "directs the transcription" of a coding sequence in a cell when RNA polymerase will bind the promoter sequence and transcribe the coding sequence into mRNA, which is then translated into the polypeptide encoded by the coding sequence.

A cell has been "transformed" by exogenous DNA when such exogenous DNA has been introduced inside the cell membrane. Exogenous DNA may or may not be integrated (covalently linked) into chromosomal DNA making up the genome of the cell. In eucaryotic cells, a stably transformed cell is generally one in which the exogenous DNA has become integrated into the chromosome so that it is inherited by daughter cells through chromosome replication, or one which includes stably maintained extrachromosomal plasmids. This stability is demonstrated by the ability of the eucaryotic cell to establish cell lines or

09560372-042800

clones comprised of a population of daughter cells containing the exogenous DNA.

09560372.1042800  
A "heterologous" region of a DNA construct is an identifiable  
5 segment of DNA within or attached to another DNA molecule that  
is not found in association with the other molecule in nature.  
For example, a sequence encoding a protein other than ABC1 is  
considered a heterologous sequence when linked to an ABC1  
promoter. Similarly, a sequence encoding an ABC1 gene will be  
10 considered heterologous when linked to an ABC1 gene promoter  
with which it is not normally associated. Another example of  
a heterologous coding sequence is a construct where the coding  
sequence itself is not found in nature (e.g., synthetic  
sequences having codons different from the native gene).  
15 Likewise, a chimeric sequence, comprising a heterologous  
structural gene and a gene encoding an ABC1 or a portion of an  
ABC1, linked to an ABC1 promoter, whether derived from the same  
or a different ABC1 gene, will be considered heterologous since  
such chimeric constructs are not normally found in nature.  
20 Allelic variation or naturally occurring mutational events do  
not give rise to a heterologous region of DNA, as used herein.

The phrase "transcriptionally modulate" infers a notion of  
directness. Thus, as used herein, "transcriptionally modulate"  
25 by a molecule means the effect upon transcription of the gene  
resulting from either (a) direct binding of the molecule to DNA  
or RNA, a DNA- or RNA-binding protein, and/or a DNA- or RNA-  
binding protein complex, or (b) direct binding of the molecule  
to a protein which directly chemically modifies a DNA- or RNA-  
30 binding protein or protein complex.

The phrase "specifically transcriptionally modulate expression"  
as used herein means modulating the expression of the ABC1 gene

without modulating the expression of other genes in the cell in a way which would cause an adverse effect on (a) an organism containing the cell in the case where the cell is within the organism or (b) the growth or the culturing of the cell, in the case where the cell is being grown or cultured to make a product where the amount of product produced is associated with expression of a gene-of-interest.

#### Vectors

- Especially preferred are virus based vectors. In the case of eukaryotic cells, retrovirus or adenovirus based vectors are preferred. Such vectors contain all or a part of a viral genome, such as long term repeats ("LTRs"), promoters (e.g., CMV promoters, SV40 promoter, RSV promoter), enhancers, and so forth. When the host cell is a prokaryote, bacterial viruses, or phages, are preferred. Exemplary of such vectors are vectors based upon, e.g., lambda phage. In any case, the vector may comprise elements of more than one virus.
- The resulting vectors are transfected or transformed into a host cell, which may be eukaryotic or prokaryotic.

The gene transfer vector of the present invention may additionally comprise a gene encoding a marker or reporter molecule to more easily trace expression of the vector.

This invention will be better understood from the Experimental Details which follow. However, one skilled in the art will readily appreciate that the specific methods and results discussed are merely illustrative of the invention as described more fully in the claims which follow thereafter.

## EXPERIMENTAL DETAILS

00560372.042800

Tangier Disease, a condition characterized by low HDL and cholesterol accumulation in macrophages, is caused by mutations in ABC1. Consistent with its role in mediating cellular cholesterol efflux, ABC1 is upregulated by cholesterol loading of macrophages. The disclosed study characterized the molecular mechanisms responsible for up-regulation of ABC1 by sterols. In cultured macrophages, ABC1 mRNA was induced in an additive fashion by 22(R)-OH cholesterol + 9-cis-retinoic acid (9CRA), suggesting involvement of nuclear hormone receptors of the LXR/RXR family. The 5' end of the human ABC1 transcript was cloned from cholesterol-loaded THP1 macrophages, and 3 new exons and an upstream start codon were found and compared to the published human cDNA sequence. Only a full length cDNA containing these 3 new exons was active in promoting cholesterol efflux when transfected into cells. When transfected into RAW macrophages, the upstream promoter (-469 bp) was induced 7 fold by 22(R)-OH cholesterol, 8 fold by 9CRA and 37 fold by 9CRA + 22(R)-OH cholesterol. Furthermore, promoter activity was increased in a sterol-responsive fashion, when co-transfected with LXR $\alpha$ /RXR or LXR $\beta$ /RXR in CV1 or HEK293 cells. Also disclosed is a sterol-responsive region of the human ABC1 promoter, along with experiments showing that it is activated by hydroxysterols and 9CRA, suggesting a mechanism involving LXR/RXR heterodimers.

The following abbreviations are used throughout this disclosure:

9CRA = 9-cis retinoic acid; 22(R)-HCH = 22(R)-hydroxycholesterol; 25-HCh = 25-hydroxycholesterol; 7-KCh = 7-ketocholesterol; DMEM = Dulbecco's modified Eagle's medium; FBS = fetal bovine serum; LPSD = lipoprotein deficient serum; G(3)PDH = Glycerol-3-phosphate dehydrogenase; LXR = liver X receptor; RXR = retinoid X receptor; SF1 = steroidogenic factor

1; HNF = hepatocyte nuclear factor; NF-~~K~~B = nuclear factor kappa B; CEBP = CAAT-enhancer-binding protein; Ap-1 = activator binding protein-1.

## 5 MATERIAL AND METHODS

### 5'RACE PCR

5'RACE PCR were performed with the SMART RACE cDNA kit (Clontech, Palo Alto, California, USA). We used 1 mg poly-A<sup>+</sup> mRNA from HEPG2 cells and THP-1 cells, differentiated into macrophage with phorbol 12-myristate 13-acetate, and exposed to acetylated LDL (25mg/ml) for 48 hours. After the reverse transcription (M-MLV Reverse Transcriptase, Life Technologies, Grand Island, New York, USA), a first PCR (hot start, 94C 30", 65C 30", 72C 3', 25 cycles then 72C 10') was performed using this reverse primer: 5'-CCCCCTCCCTCGGGATGCCGACAGACAA-3' (SEQ ID NO: 8).

A second PCR (hot start, 94C 30", 55 C 30", 72 C 3', 25 cycles then 72C 10') was done on 2.5ml of the 50 times diluted first PCR sample with the nested primer: 5'-GCCTCCGAGCATCTGAGAACAGGC (SEQ ID NO: 9). The forward primers are provided by Clontech kit. The different bands obtained by PCR were cloned in TOPOTA cloning vector (Invitrogen, Carlsbad, California, USA) and sequenced.

25

### Cloning of hABC1 promoter and intron 1 and 2

The screening of the human RPC.11 BAC clones library was performed (Research Genetics, INC, huntsville, AL, USA) with a 68mer oligo probe corresponding to the base 11 to 79 of the published hABC1 sequence (genebank accession number NM\_005502). 5 BAC clones gave a strong hybridization signal. 2 of them were

00550372.042800

positive by PCR for exon 1 (BAC553F19, primers 5'-  
TAATTGCGAGCGAGAGTGAGTGGG-3' (SEQ ID NO: 10) (forward), 5'-  
CCTACCCCTTGACAAGCCTTCC-3' (SEQ ID NO: 11) (reverse)) and exon  
3 (BAC 522C12, primers 5'-GGTTGTGTGTATTTAGCACAGCAGGTTGG) (SEQ  
5 ID NO: 12) (forward), 5'-TGCTTCCTATCGTGCTTTATCTGGTTCAC-3' (SEQ  
ID NO: 13) (reverse)). After digestion by PstI, a southern blot  
was performed using the <sup>32</sup>P radiolabelled probes generated by PCR  
with the previously cited exons. Positive bands were cloned in  
pBluescript KS(+) (Stratagene, La Jolla, California, USA). A  
10 colony hybridization (probes used for southern blot) (30)  
allowed us to isolate positive clones for the hABC1 promotor (5  
kb) and intron 2. Serendipitously, the sequencing results  
(performed on both strands) showed that we cloned also intron  
2 from BAC 522C12. The sequences of these introns are contained  
15 in the sequence of human genomic clone RP11-1M10 (Genebank  
accession number AC012230) wich contains exon 1 (3463 bp to 3679  
bp), exon 2 (147555bp to 147715bp) and exon 3 (160429 bp to  
160801 bp).

## 20 Cell cultures and transfection experiments

The cell lines were purchased from ATCC (Rockville, Maryland,  
USA). The murine RAW 264.7, African green monkey CV-1, and  
human 293 or HepG2 cell lines were maintained in Dulbecco's  
modified Eagle's medium (DMEM) with 10% Fetal Bovine Serum  
25 (FBS), 100 U/ml penicillin and 100 mg/ml streptomycin. THP-1  
cells were maintained in RPMI-1640 containing L-glutamine, 10%  
heat inactivated FBS, 100 U/ml penicillin and 100 mg/ml  
streptomycin supplemented with 0.5mM β-mercaptoethanol.  
Confluent cells were differentiated with 0.2 mM phorbol 12-  
30 myristate 13-acetate (Sigma Chemical Co., St Louis, Missouri,  
USA) in ethanol during 72 hours. Thioglycollate-elicited  
peritoneal macrophages were isolated from C57 B1/6 mice as  
described (31).

09560372-042800

Transfections were performed in 24-wells plates with Lipofectamine reagent (transactivation experiments in CV-1 and 293 cells, fig. 6-7) or Lipofectamine-Plus reagent (Basal activation experiments in RAW 264.7, fig. 5) according to the manufacturer's instructions (Life Technologies, Grand Island, New York, USA). For basal activation experiments a total of 0.15 mg of reporter DNA and 0.05 mg of PRL-CMV(Renilla) (Promega corp., Madison, Wisconsin, USA) per well were used. For transactivation studies we used, per well, 0.025mg of PRL-CMV, 0.2 mg of reporter DNA and 0.1mg of each receptors (CMX-hRXR $\alpha$ , CMX-hLXR $\alpha$ , CMV-mLXR $\beta$ ) or 0.2 mg of pcDNA3. The transfected cells were cultured in lipoprotein deficient serum (LPDS) medium in the presence of 4 mg/ml of 22(R)-hydroxycholesterol (22(R)-HCh), 25-hydroxycholesterol (25-HCh) or 7-ketocholesterol (7-KCh), 10 mM 9-cis retinoic acid (9CRA) (Sigma Chemical Co., St Louis, Missouri, USA) or ethanol alone for 24 hours. The luciferase activities were measured using Promega Dual Luciferase assay system. Reporter plasmid used to analyse the activity of hABC1 promoter was constructed by subcloning a 1029 bp PCR fragment of hABC1 promoter (-928 bp +101 bp) into pGL3-Luc basic vector (Promega). The sequence of the PCR fragment was verified. A shorter promoter (-469 bp to +101 bp) was generated by digestion of this plasmid with SacI. Where shown, error bars represent the standard deviation.

25

#### Northern blot analysis

Cells were cultured and treated according to the paragraph "cell cultures and transfection experiments". Total RNA were isolated with RNazol B reagent (TEL-TEST, Inc., Friendwood, texas, USA). Northern blots were performed as described elsewhere (30). A human ABC1 probe corresponding to exon 2 to 8 of the published sequence was synthesized by RT-PCR (5'-AGGTGGCCTGGCCTCTATTTATCTTC-3' (SEQ ID NO: 14) (forward) and 5'-

GCCTCCGAGCATCTGAGAACAGGC-3' (SEQ ID NO: 15) (reverse). LXR probes are synthesized from human LXR $\alpha$  and mouse LXR $\beta$  sequences (25), (32). mouseG(3)PDH probe was used as an internal standard (RT-PCR synthesized fragment, primers: 5'-  
5 ACCACAGTCCATGCCATCAC-3' (SEQ ID NO: 16) (forward), 5'-  
TCCACCACCCTGTTGCTGTA-3' (SEQ ID NO: 17) (reverse)).

### Informatics analysis

Nucleotide sequences were analysed using "Sequence Tools"  
10 ([http://www.path.cam.ac.uk/~pd213/tool\\_multi.html](http://www.path.cam.ac.uk/~pd213/tool_multi.html)) and BLAST from NCBI (<http://www.ncbi.nlm.nih.gov/BLAST/>). The search for transcription binding sites was performed by MatInspector public domain (<http://genomatix.gsf.de/cgi-bin/matinspector/matinspector.pl>).

15

## **RESULTS**

### Increased ABC1 mRNA in human macrophages treated with sterols and/or retinoic acid.

To investigate the activation of the endogenous ABC1 gene by  
20 oxysterols and/or retinoic acid in macrophages, we performed Northern blot analysis of total RNA from human THP-1 macrophages. Figure 1 shows a significant increase of ABC1 mRNA in cells treated with 22(R)-HCh (2 fold induction,  $P < 0.05$ ) or 9CR (2 fold,  $P < 0.05$ ). An additive effect was obtained with  
25 combined treatment (4 fold,  $P < 0.05$  when compared with separate treatments).

### Characterization of the 5'end of the hABC1.

In order to identify the promoter of the human ABC1 gene, we  
30 performed 5' RACE PCR using poly-A<sup>+</sup> mRNA from cholesterol loaded THP-1 macrophages and HepG2 cells (fig. 2B). This revealed a

09560372.042800

single major transcript (A) consisting of a first exon of 217 bp followed by a second exon of 160 bp, 73% identical to mouse exon 1 (genebank accession number X75926). This exon is then followed by the published human exons 2, 3, 4 (genebank accession number NM\_005502).

In HepG2 cells 5' RACE PCR revealed 3 different transcripts (fig. 2B). Transcript B represents a truncated version of exon 2 found in THP-1 cells (only the 29 last bases) followed by the published exon 2, 3, 4. Transcript C contains one exon of 372 bp upstream of the published exon 2, different to the exons found in THP1 cells. Transcript D has the same 5' structure as transcript C but lacks the published exon 3.

15 A Blast search in the Genebank database (htgs) revealed 100% homology of these exons (1-3, fig. 2A) with fragments of the human genomic clone RP11-1M10 (working draft sequence, genebank accession number AC012230 ). A comparison of the sequence from the published exon 2 (genebank accession number NM\_005502) and  
20 the 5'RACE PCR product and RP11-1M10 revealed a C instead of a T at position +15 and a G instead of a A at position 17.

Conceptual translation of the transcripts, revealed two new start codons, in frame with the previously published ATG located  
25 in exon 5 (11) (fig. 2A, C). In the case of the transcript characteristic of THP1 cells, a new ATG, located in exon 2, resulted in an extra 60 amino-acid peptide. In the case of HepG2 cells, a new start codon, at the 3' end of exon 3 may be functional in transcript C and also transcript D, which lacks  
30 the previously published start codon. This results in an extra 39 amino acid peptide for transcript C.

09560372-042800

A comparison of the putative N-terminal amino acid sequences of ABC1 (transcripts A, B) with nucleotide databases revealed strong homology to the N-terminal sequence of two members of the ABC1 family (57% identity with ABCR and 45% identity with ABC3 (fig. 2C). This strongly suggest that this N-terminal sequence of hABC1 is authentic.

Sequence of hABC1 promoter.

The promoter region upstream of exon 1 was responsive to sterols when transfected into cells (see below), while the 2.3 kb region upstream of transcript B was not responsive (data not shown). Thus, we focused our attention on the former region.

Figure 3 presents a partial sequence of genomic DNA with a fragment of exon 1, cloned from the human RPCI.11 BAC library. A potential TATA box element is present at -32 bp and an Sp1 site at -101 bp. An analysis of this sequence revealed several potential binding sites for different transcription factors: C/EBPB, NF-KB, GATA1, HNF3B, NF1. There was no obvious consensus element for LXR/RXR (DR1 or DR4). However it is known that these nuclear receptors can bind degenerate elements, as shown for the CETP promoter (22).

hABC1 promoter is functional and sterol responsive in macrophages.

To investigate the function of the potential hABC1 promoter, we transfected the macrophage-like RAW 264.7 cell line with a promoter-luciferase construct (figures 5A and 5B). We used 9CRA as an activator of endogenous RXR, and 22(R)-HCh, which is a good activator of LXR-RXR (33) and a poor activator of SF1 (24).

Compared to basal conditions, transfected cells treated with 22(R)-HCh or 9CRA exhibit 7 fold and 8 fold higher promoter

09560372.042800

activity , respectively ( $P < 0.001$ ) (figure 5A). When both compounds are added together, there was a synergistic 37 fold induction ( $P < 0.001$ ). A similar response was obtained with promoter fragments containing 928 bp or 469 bp of upstream 5' sequence (fig 5B).

Next we compared the response of the ABC1 promoter to different sterols (fig. 5C). We treated the transfected cells with 25-HCh which is a good activator of SF-1 and a poor activator of LXR 10 (24). We also treated them with 7-KCh which is relatively abundant in human arterial foam cells (34). 25-HCh is a poor inducer of the hABC1 promoter compared to 22(R)-HCh (1.5 fold activation,  $P < 0.05$ ). No significant effect of 7-KCh was detected. However, when added in combination with 9CRA, a 15 significant additive effect is detected for 7-KC (2 fold when compared to 9CRA alone,  $P < 0.01$ ). This pattern of sterol responsiveness is consistent with a transcriptional mechanism involving LXR.

#### 20 LXR $\alpha$ and LXR $\beta$ are both expressed in macrophages

To further investigate the potential role of LXR $\alpha$  and LXR $\beta$  in the upregulation of hABC1 we verified that the mRNAs of these nuclear receptors were present in RAW264.7 cells (figure 4). We also analysed their expression in vivo, using thioglycollate- 25 elicited peritoneal macrophages from mice. Both receptors were detected in macrophages by Northern blot of total RNA, with a stronger signal for LXR $\beta$ . We also selected two cell lines for our transactivation experiments: CV-1 and 293 cells. As shown in figure 4, both LXR $\alpha$  and LXR $\beta$  could be detected in 293 cells, 30 and LXR $\beta$  was detected in CV1 cells.

00560372.042800

LXR/RXR activates the  
hABC1 promoter in 293 and CV-1 cells.

In order to define the involvement of hRXR $\alpha$  and/or LXR $\alpha/\beta$  in the sterol upregulation of hABC1, we cotransfected 293 cells with the human ABC1 promoter and with these receptors (fig. 6). We used a shorter promoter (deletion -460), which was sterol-responsive in macrophages (figure 5C). In 293 cells, without transfected LXR/hRXR, we obtained an upregulation of the promoter by 22(R)-HCh (4.5 fold,  $P < 0.05$ ) and 9CRA (3.5 fold,  $P < 0.05$ ) alone. The combination of 9CRA and 22(R)-HCh resulted in an additive effect (10 fold,  $P < 0.05$ ). When LXR $\alpha$ /hRXR $\alpha$  were transfected, basal activity was slightly increased (1.5 fold), as was the sterol response, but there was no additional effect of 9CRA or 9CRA+ 22(R)-HCh. However, transfection of LXR $\beta$ /RXR $\alpha$  caused a 5 fold increase in basal expression and a synergistic effect of 9CRA+22(R)-HCh (19 fold when compared to ethanol and 3 fold when compared to 9CRA alone,  $P < 0.05$ ).

As a positive control for these experiments we used a construct containing 3 copies of the LXR/hRXR $\alpha$  binding site of the CETP promoter (22). Even in the absence of transfected receptors, this construct is highly sterol and retinoic acid responsive in 293 cells (14 fold and 24 fold increase in luciferase activity,  $P < 0.05$ ) and an additive or synergistic effect (58 fold) is obtained with cotreatment. The LXR transfection experiments result increased basal activity and increased induction by sterols. However, 9CRA provide no further increase in activity compared to non-transfected cells. These results suggest that endogenous LXRs, in 293 cells, play a role in the response of both ABC1 and CETP promoters with a further increase in sterol-dependent promoter activity when LXR/RXR are transfected.

In CV-1 cells a significant sterol-activation of the promoter

008240.269560

was detected without transfected receptors (4 fold,  $P < 0.01$ ). Cotransfection with hRXR $\alpha$ /LXR $\alpha$  or hRXR $\alpha$ /LXR $\beta$  increased the basal activity of the promoter (2 fold and 4 fold, both  $P < 0.01$ ). Exposure to 22(R)-HCh resulted in increased transactivation of the promoter (6 fold and 8 fold), compared to the control with no receptor.

The full length form of the cDNA, incorporating exons 1-3 (figure 2A), was active in promoting cellular cholesterol efflux (figure 8B) while the shorter form, reported previously (8a, 8b, 9-12, 14) was inactive (figure 8A).

## DISCUSSION

The described study has identified a region of the human ABC1 promoter, which is active in macrophages and is induced by 22 (R)-HCholesterol and 9-cis retinoic acid. The characterization of the major transcript in cholesterol-loaded THP1 macrophages led to the identification of this promoter, and also showed that most upstream ATG in the previously published cDNA (18) does not represent the authentic translation initiation site. Previous functional studies using this cDNA were describing the properties of a protein fragment truncated in the signal peptide, and we will need to be re-assessed with full length cDNA, as described herein. Our expression studies also verified that only the full length cDNA containing the new exons 1-3 (Figure 2) was functionally active in promoting cellular cholesterol efflux (Figure 8). The pattern of activation of the hABC1 promoter by specific oxysterols and 9CRA, as well as the transactivation experiments, strongly implicate LXR/RXR heterodimer in increasing transcription of the ABC1 gene. Thus, LXR and/or RXR agonists could be useful drugs to reverse foam cell formation and atherogenesis.

09560372.042800

The mechanism of upregulation of ABC1 by acLDL (18) has not been studied. Our results with promoter-reporter constructs implicate a transcriptional mechanism. The 928bp fragment of promoter we cloned is sufficient for a basal expression of ABC1 in macrophages and its upregulation by oxysterols and retinoic acid, separately or synergistically. Several lines of evidence indicate a role for LXRs in the sterol-mediated activation of hABC1: 1) 22(R)hydroxycholesterol or 25-HCh and 9CRA activate the hABC1 promoter alone or in a synergistic fashion (25, 29), 2) 22(R)hydroxycholesterol is a more potent inducer than 25-HCh, in accordance with the literature (33) and different to the characteristics of the activation of another oxysterol-activated nuclear receptor, SF1 (24), 3) LXR $\beta$  and LXR $\alpha$  are endogenously expressed in RAW264.7 cells, in thioglycollate-elicited peritoneal macrophages and in fresh human monocyte-derived macrophages (Yu Sun and A. Tall, unpublished results), 4) LXR $\beta$ /hRXR $\alpha$ , and to a lesser extent LXR $\alpha$ /hRXR $\alpha$ , activate the ABC1 promoter when cotransfected in CV-1 and 293 cells.

The pattern of activation of the ABC1 promoter by sterols suggests that its expression may be suboptimal in atherosclerotic lesions. Thus, 7-KCh is relatively abundant in oxidized-LDL and in atheroma foam cells (37), and is a poor activator of the hABC1 promoter (Figure 5C). 27-HCh, also abundant in foam cells, is a relatively poor activator of LXR (32,36). Thus, the accumulation of oxysterols in atherosclerotic lesions probably does not result in optimal activation of hABC1. This suggests that small molecules that are optimal LXR activators might be effective drugs at reversing foam cell information, and that they might be useful as a treatment for atherosclerosis. The activation of the hABC1 promoter by 9CRA is increased 2 fold when given with 7-KCh (fig. 5C). This further suggests that, with regard to the induction of ABC1 by oxysterols, an unfavorable foam cell environment

009560372-042800

could also be switched to a more favorable one by delivery of ligands for RXR.

The inability of LXR $\beta$  to compensate for the lack of LXR $\alpha$  in -  
5 LXR $\alpha$ -/- mice (21) suggests that these receptors have different  
targets. In vitro, both LXR $\alpha$  and LXR $\beta$  are able to upregulate  
hABC1 (figs. 5 and 6) or CETP (22), but LXR $\beta$  is clearly more  
effective than LXR $\alpha$  in mediating the sterol response of ABC1.  
This also is consistent with the fact that LXR $\beta$  appears to be  
10 more highly expressed than LXR $\alpha$  in macrophages (fig. 5).

The hABC1 promoter contains several potentially interesting  
transcription factor binding sites (fig. 3). A CREBP1-CJUN  
element, at -1039, could be responsible for the upregulation of  
15 ABC1 by cAMP obtained in human fibroblasts (8). Atherosclerosis  
involves inflammatory processes (35). In foam cells, the efflux  
of cholesterol is down regulated and its trafficking modified  
by interferon gamma (36). ABC1 has also been implicated in the  
secretion of the proinflammatory cytokine Il-1 $\beta$  (37).  
20 Macrophages and fibroblasts treated with Il-1 $\beta$  exhibit a makedly  
increase of cholesterol efflux to lipid-free apolipoprotein AI  
(38). Therefore it is interesting to note several potential  
binding sites for transcription factors such as Nuclear Factor  
Kappa B or AP-1, mediators of the Il-1 $\beta$  response (39). These  
25 factors have also been implicated in the response to oxidized  
LDL, but are probably not involved in the induction of hABC1  
mRNA by oxysterols, since the truncated promoter, lacking these  
sites was equally as active as the longer promoter (fig. 5B).

30 The results of the 5'RACE PCR suggest that the hABC1 gene can  
be spliced into different transcripts. Whether this splicing

09560372.042800

has a physiologically significant role is not known. It seems that the cholesterol loading of macrophages results in the synthesis of one major transcript, also present in HEPG2 cells among a more heterogenous hABC1 mRNA population. Every 5 transcript we found possesses a start codon upstream of exon 4 which excludes the previously published start codon (11) and rather makes exon 4 a good candidate for the signal peptide. Because mRNAs starting from exon 3 are present in HEPG2 cells, we cannot exclude the presence of one or two other active 10 promoters, upstream of exon 2 and 3.

To conclude, we have shown that hABC1 is upregulated at a transcriptional level by oxysterols and 9CRA through a DNA element located between -469 bp to +101 bp (fig. 2). This 15 activation is likely to involve the nuclear hormone receptor LXR $\beta$ /RXR but further studies will be needed to show whether this is a direct effect on the promoter, or is mediated by an indirect mechanism. Although the relevant region of the hABC1 promoter does not contain an obvious LXR binding region, such 20 sequences can be occult (22). These results provide strong support for the idea that LXRs may help to coordinate different steps in reverse cholesterol transport (22). For example, CETP activity results in the remodeling of HDL into small particles and liberates free apoA-I from HDL (40). Small HDL and free 25 apoA-I appear to be the optimal substrates for ABC1 (41). Thus, coordinate induction of CETP and ABC1 by LXR $\beta$ /RXR might act synergistically to enhance cholesterol efflux from macrophage foam cells.
